RF fingerprinting on NFC devices

Intermediary report

Not confidential

Student: Luc Wachter

Project proposed by: Joël Conus
Kudelski Group SA
22-24, Route de Genève
1033 Cheseaux-sur-Lausanne

Teacher in charge: Alberto Dassatti

Academic year: 2019-2020

Yverdon-les-Bains, 10th June 2020

1 Scope statement

Scope statement for RF fingerprinting on NFC devices (Bachelor Thesis)

Project purpose: Develop a tool to identify NFC devices by analysing the RF spectrum of their transmitted signals

Duration: 450 hours (ends 31st July 2020)

Detailed description

RF fingerprinting is a technique that allows the identification of radio transmitters (such as IoT devices) by analysing the spectrum of their transmissions. This analysis can typically be performed using machine learning algorithms.

NFC technology is often used in access control and payment applications but many implementations are vulnerable to relay attacks with research and tools that facilitate such attacks being publicly available.

The goal of this project is to determine if RF fingerprinting could be used as an authentication technique against relay attacks.

The main steps of this project are the following:

- Build a simple lab setup with Software-Defined Radio (SDR) equipment to acquire signals between an NFC device and its reader
- Acquire RF spectrum data of various NFC devices
- Analyse the signals
- Classify the signals of the devices by using supervised machine learning classification techniques in order to differentiate trusted devices from attacker / relay devices
- Determine if this identification technique could be used as an authentication feature against relay attacks

As the receiving equipment (SDR) has an influence on the recorded signals, for this project we consider a single receiver to record the RF samples. Similarly, the lab setup should be built to provide an ideal low-noise & low-interference environment to simplify the analysis phase.

The expected deliverables are the following:

- A tool able to identify NFC devices by analysing the RF spectrum of their signals, at least in an ideal environment and with a small number of devices
- A detailed account of the steps taken and the setup used (as part of the report)
- An analysis of the results (as part of the report)

Collaboration with other researchers in this field is wished (EPFL, ElectroSense).

Table of contents

2 Introduction

2.1 Project description

Radio Frequency (RF) fingerprinting is a technique that allows the identification of radio transmitters by extracting small imperfections in their spectrum. These imperfections are caused by tiny manufacturing differences in the devices' analog components. Using Software-Defined Radio (SDR) equipment, we can analyse this spectrum in order to extract the aforementioned differences and identify a device.

Such techniques can be used on any type of radio transmission: Bluetooth, BLE, WiFi, LTE, etc. This project aims to use RF fingerprinting on NFC devices. Indeed, NFC is often used in access control and payment applications but many implementations are vulnerable to relay attacks. Spoofing the imperfections in an emitter's radio spectrum is close to impossible at the present time, since it is essentially a hardware signature. This is why a technique like the one described here would be a valuable additional security layer.

The goal of this project is to determine whether applying machine learning techniques to the problem of RF fingerprinting NFC devices could be used as an authentication technique, in order to prevent relay attacks. If a dataset of sufficient quality and variety can be produced, it could be another outcome of the project. Indeed, while some exist for 802.11 communications, no dataset seems to be available for raw recordings of NFC transactions.

2.2 Context

This project is conducted in the context of my bachelor thesis at HEIG-VD.

- Department: Information and communication technologies
- Faculty: Information technology and communication systems
- Orientation: Software engineering

It was proposed by Mr Joël Conus of Kudelski Group SA.

2.3 Document description

This intermediary report marks the middle of the project. Because of this, it is firmly anchored in the analysis and conception phases, which means much of what is presented is subject to change in the second half of the project.

Nevertheless, this document describes the research done while studying the state of the art. It then presents the acquisition setup and the results it brought, before showing the steps undertaken to validate the captured signals through decoding. Finally, it showcases the first conception ideas and decisions made for the learning model, in light of our study of the state of the art.

3 State of the art

3.1 Taxonomy

It is certainly useful to start with a review of the different ways to categorize the features and algorithms used by researchers in the field. The goal is to define our needs precisely and select the important things to consider.

3.1.1 Taxonomy for features

The features we select must allow us to identify a precise device among potentially very similar devices. We need what Delgado et al. [1] describe as a Physical Unclonable Function (PUF). PUFs are physical distortions that are unique to a specific system. They are another way of talking about fingerprints.

Xu et al. [2] propose three ways to categorize radio signal features:

- based on the specificity of the feature (from vendor specific to device specific),
- based on the layers (PHY, MAC, Network and higher),
- and based on the acquisition method (passive or active).

Whether we end up with a system that is able to identify many devices uniquely, or one that only tries to separate a specific device from the others, we will need device specific accuracy. We don't want to make relay attacks impossible only if the attacker doesn't use a device from the same vendor as the victim's device.

Features from the MAC and higher layers typically require in depth knowledge of the protocols in play. Not only that, but they also tend to be less specific than we would like (either vendor specific or depending on the type of device). This indicates we should probably focus on the physical (PHY) layer features, which rely on imperfections in the manufacturing process of the devices.

3.1.2 Taxonomy for fingerprinting algorithms

Riyaz et al. [3] provide a visual categorization of fingerprinting approaches, which we adapt in figure 1. We take a look at these approaches in the following paragraphs.

Supervised approaches: Supervised approaches use features from labelled data to generate a function capable of separating the different classes. These approaches can be further categorized in similarity based and classification techniques.

Similarity based techniques are white-list algorithm that use a database of fingerprints and a similarity measure to determine whether a device is legitimate. Developing a technique like this requires prior knowledge of vendor specific device features [3]. Classification systems can also require deep knowledge of the features and protocols used, in the case of "traditional", manually tuned classifiers. Those are built to extract predetermined features and work similarly to other white-list algorithms afterwards.

The classification algorithms we are most interested in are deep learning techniques, which are able to extract the features they need by themselves. This can be done through deep Multi-Layer Perceptrons (MLP) [1, 4] or through more advanced techniques like Convolutional Neural

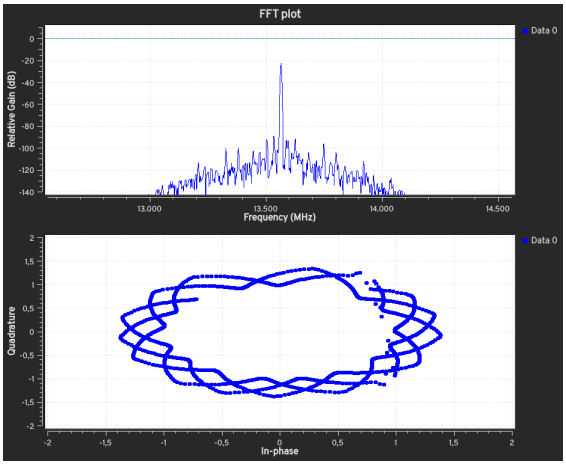

Figure 1: Fingerprinting algorithms taxonomy

Networks (CNN) [3, 5, 6, 7, 8]. The latter have proved very powerful in domains like computer vision, natural language processing and recommendation systems. This success is one of the reasons experimentations on CNNs are common in RFML research.

Unsupervised systems: Unsupervised approaches cannot by themselves discriminate a legitimate device from an illegitimate one. They don't have that information, since they work with unlabeled data. In order to detect attempts of impersonation, such a system has to keep a record of fingerprints and linked identifiers. It can then throw an alert when multiple fingerprints are linked to the same MAC address or when multiple MAC addresses are linked to the same fingerprint.

Xu et al. [2] specify that unsupervised approaches are appropriate when the fingerprints of legitimate devices are not available. ... are examples of work on such systems.

3.2 Features selection

In section 3.1.1 we discussed the different types of features that exist in radio signal data. We concluded that the features we are most interested in are from the physical layer.

What about [pre 6, page 2]?

I love[1].

- **Waveform domain techniques** [11], [14], [22], [24], [25] consider time and frequency representation as the basic blocks while **modulation domain techniques** [6] represent signals in terms of I/Q samples. - Waveform domain techniques are more flexible but more complex. Modulation domain techniques are better structured and well-behaved but require knowledge of the respective modulation scheme.

4.4 Dataset description

An early observation here is that interferences are not as troublesome as they are when working on WiFi fingerprinting. Because of the frequency used by NFC and the necessity for proximity, a lot of interference sources... *Furthermore, channel variation problems are tied to coding methods that use subcarriers (like OFDM) and don't affect NFC.*
